Nymak Pharma Website: Why It Needs a VPS and Not Our Existing cPanel Hosting

> **The one-line answer:** our new website is not a set of static pages. It is a running application that needs a computer of its own, with programs working in the background around the clock. Shared cPanel hosting does not allow that. A VPS is simply "our own small computer on the internet", and it costs about the same as we already pay for hosting.

1. What we built, in plain words

The new Nymak Pharma website is a **custom-built web application**, not a template site like typical WordPress pages. Behind what visitors see, the server runs two permanent background jobs:

- **A "page builder" that pre-builds every page for Google.** When a visitor or a search engine asks for a page, this program assembles the finished page instantly, including the French and Spanish versions, the product catalogue, and all the search-engine signals (sitemap, language tags, structured data). This is what makes the site fast and **properly visible on Google**. It must be running continuously, 24 hours a day.
- **A "mail room" that handles enquiries in the background.** Contact-form submissions, emails and other tasks are queued and processed by a second permanent program so visitors never wait.

Think of it like a factory: the website isn't just the product on the shelf. It's the machines behind it, and those machines have to keep running even when nobody is looking.

2. What cPanel shared hosting actually is

Our existing cPanel hosting is **shared hosting**: one physical server is divided between hundreds of customers, like renting a desk in a crowded shared office. It's cheap and fine for simple websites, but the house rules are strict:

1. **You cannot install software.** The server forbids installing the tools our site needs (most importantly, the runtime that powers the page builder described above).
2. **Nothing may run in the background.** Any program left running for more than a few minutes is automatically shut down by the host, so both background jobs our site depends on would be killed.
3. **You cannot change the server's settings.** PHP version, memory limits and extensions are all fixed by the host for everyone on the box.
4. **You share everything.** If another customer on the same server gets busy or gets hacked, our site slows down or is exposed too.

It isn't that cPanel is bad. It was built for a different era of websites: pages that simply display a file when asked. Our site needs a server that can *run software*, not just *serve files*.

3. What a VPS is, in one paragraph

A **VPS (Virtual Private Server)** is our own dedicated slice of a professional datacentre computer, with private memory, storage and processing power under our full control, like leasing our own small office instead of a desk in a shared one. We decide what runs on it, it stays on 24/7, and nobody else's websites can interfere with ours. It is the standard, normal way business applications like this are hosted. Nothing exotic or expensive.

4. Side-by-side comparison

What the site needs	cPanel shared hosting	VPS
Install required software	Not allowed	**Yes, full control**
Programs running 24/7 in the background	Automatically killed, not possible	**Yes, normal behaviour**
Pages pre-built for Google (SEO)	Cannot run the program that does it	**Yes, works as designed**
Enquiry queue and background jobs	Crippled (cron workarounds only)	**Yes, reliable**
Choose PHP version & settings	Fixed by the host	**Our choice**
Updating the site	Manual file uploads, slow and error-prone	**One-command, automated deploys**
Performance & security isolation	Shared with hundreds of strangers	**Private, our resources only**
Typical monthly cost	$3-6	**$6-12 for our size**

5. Why this matters in business terms

- **Google ranking.** The site was engineered so search engines see fully rendered pages in all three languages. That is the entire SEO investment. On shared hosting the program that does this cannot run, so rankings, link previews on WhatsApp/LinkedIn, and multilingual indexing all degrade. We would pay for SEO engineering and then switch it off to save a few dollars a month.
- **Enquiries.** Buyer enquiries are processed by the background "mail room". On shared hosting it can't stay alive, so enquiries risk delays or loss.
- **Speed and stability.** On shared hosting we compete for resources with hundreds of unknown websites. On a VPS, performance is ours alone and consistent.
- **Security.** For a pharmaceutical company's public face, an isolated server with our own firewall is a meaningfully safer posture than a crowded shared box.
- **Maintainability.** Updates deploy cleanly and repeatably on a VPS. On shared hosting every update is a manual FTP upload, which is slower and easier to get wrong.

6. "Can't we just make cPanel work somehow?"

Partially, by building the site offline, uploading files manually, and switching off the parts that need background programs. The site would still open in a browser, but we would lose exactly what we paid to build: the Google visibility, the reliable enquiry pipeline, and painless updates. The saving is about $5-8 per month against those losses. A false economy.

7. Local (Indian) providers: roughly ₹10,000-15,000 per year

We don't have to buy from a foreign provider. Several established **Indian hosting companies sell the same kind of VPS**, billed in rupees with GST invoices, and with datacentres inside India, which also means slightly faster response times for Indian visitors. A suitable plan (2 GB memory or more) typically works out to **about ₹10,000-15,000 per year** (roughly ₹800-1,250 a month), in line with international VPS pricing.

Popular local providers to compare: MilesWeb, E2E Networks, Hostinger India, ZNetLive, BigRock and GoDaddy India. E2E Networks in particular is a listed Indian cloud company (MeitY-empanelled) with Delhi and Mumbai datacentres, a strong fit where data-residency or GST billing matters.

8. What it costs: international VPS providers

We need a modest server: **2 GB of memory or more** (entry-level laptop territory) is comfortable for this site. Prices below are each provider's published entry rates; links go to the live pricing pages.

Provider	Plan	What you get	Monthly cost	Pricing page
Hetzner Cloud	CX23	4 GB memory / 40 GB storage	€5.49 (≈ $6.50)	hetzner.com/cloud
DigitalOcean	Basic Droplet	2 GB memory / 50 GB storage (1 GB option: $6)	$12	digitalocean.com/pricing/droplets
Vultr	Cloud Compute	2 GB memory / 55 GB storage (1 GB option: $5)	$10-12	vultr.com/pricing
Linode (Akamai)	Nanode	1 GB memory / 25 GB storage	$5	linode.com/pricing
AWS Lightsail	Bundle	2 GB memory / 60 GB storage (1 GB option: $7)	$12	aws.amazon.com/lightsail/pricing
Hostinger VPS	KVM 2	8 GB memory / 100 GB storage	$8.99 renews $14.99	hostinger.com/pricing/vps-hosting

		prepaid 2-yr promo; renews higher		
OVHcloud	VPS	entry VPS plans	from ~$5	ovhcloud.com/en/vps

All of these are established, reputable providers used by millions of businesses. Hetzner prices are for EU datacentres in euros; USD figures are approximate. Hostinger's rates are prepaid promotional pricing that renews at a higher rate.

9. Recommendation

Since we're comfortable managing a Linux server ourselves, **a plain VPS is all we need**. No management panels or managed-hosting premiums required. Total cost lands around **₹10,000-15,000 per year** with an Indian provider, or $6-12/month internationally.

Suggested pick: an Indian provider such as **MilesWeb or E2E Networks** if we want rupee billing, GST invoices and an India datacentre; or **Hetzner / DigitalOcean** (Bangalore DC available) for the best global value. Any of these comfortably runs the entire website with room to grow.

If we ever decide we don't want to manage the server, "managed" options exist (Laravel Cloud from ~$5/mo + usage, Cloudways from ~$11-24/mo). They run the server for us at a higher price. Not needed while we handle Linux ourselves.

Prices verified on each provider's public pricing page at the time of writing and may change; promotions and taxes vary by region. Links above open the live pricing pages for current figures.
